

Sample Tab

5 This application is a Continuation in Part Application of United States application 09/958,933 filed on May 11, 2000, claiming priority to 60/133,876 filed May 12, 1999.

10 The invention relates to a tab for retaining a sample for analysis. More particularly, the present invention provides an apparatus and method for sample analysis using a variety of instruments including spectrophotometric or microscopic analysis.

BACKGROUND OF THE INVENTION

15 Rapid methods for analysis of a compound or a substance of interest within a biological or non-biological sample are desired within the art.

20 For example, U.S. 4,575,240, U.S. 4,134,678 and U.S. 4,734,260 disclose sample chambers for fluid analysis within automated analysers. In U.S. 4,575,240, the sample chamber is complex, comprising input and output ports for adding a fluid sample into a reservoir formed within a prism that is sealed against a window through which light passes through. A spring attached to a door of the chamber is provided so that when the door is closed, the spring urges the prism against a sealing member. U.S. 4,134,678 discloses an on-line cuvette that can be used within an automated analyser comprising sample input and output ports.

25 U.S. 4,734,260 discloses a cuvette for liquid sample analysis comprising a thin sample chamber delimited by radiation transmitting members. The chamber is made from a plurality of component parts that when assembled form the cuvette. Ports extend into, and out of, the sample chamber for sample injection and withdrawal. The ports pass through a housing and one of the radiation transmitting members. Plugs are provided to seal the ports after a sample has been introduced into the cuvette.

30 U.S. 5,430,542 discloses a simplified disposable cuvette made of two transparent plastic cover sheets that are adhesively attached to a third thicker plastic sheet comprising a sample cavity. The disposable cuvette comprises input and output ports, with the input port adapted to be attached to a syringe for sample introduction. Again, only fluid samples may be analysed using this disposable cuvette.

There is a need for a sample chamber that is easy to use and adaptable for a range of applications, including the analysis of semi-solid and fluid samples. It is an object of the present invention to overcome disadvantages of the prior art.

5

The above object is met by a combination of the features of the main claims. The sub claims disclose further advantageous embodiments of the invention.

10 **SUMMARY OF THE INVENTION**

The present invention relates to a sample tab for retaining a sample for analysis.

15

The present invention provides a sample tab comprising, a base plate having a top surface and a bottom surface, at least a portion of the base plate adapted to permit transmission of electromagnetic radiation therethrough, a well disposed on the top surface of the base plate for retaining a sample, the well defined by a closed wall extending above the top surface of the base plate, and a cover plate, hingedly attached to the base plate, and moveable between an open and a closed position, wherein at least a portion of the cover plate permits transmission of electromagnetic radiation therethrough, so that when the cover plate is in the closed position an optical path is formed through the portion of the base plate that permits transmission of electromagnetic radiation, the well, and the portion of the cover plate that permits transmission of electromagnetic radiation. Another embodiment of the invention permits the electromagnetic radiation to be reflected off the opposite side of the sample tab, thereby doubling the direct pathlength.

30

The present invention also provides for a sample tab as described above wherein the closed wall comprises one or more overflow openings, the closed wall surrounded by a containment wall defining an overflow ring therebetween.

35

The cover plate may be attached to the base plate or may be separate. Further, the sample tab may comprise a locking member that associates with a corresponding mating member, thereby permitting the cover plate to be attached to the

base plate. The locking member may comprise, but is not limited to, a circular ring capable of frictionally engaging an outer portion of a containment wall or one or more clips capable of frictionally engaging and attaching the cover plate to the base plate. The locking members may be located on the base plate, cover plate or both the base plate, and the cover plate. Similarly, the associated mating member that receives the locking member may be located on the base plate, cover plate or both the base plate, and the cover plate.

Also provided by the present invention, there is provided a sample tab as defined above wherein the wall is surrounded by a containment wall defining an overflow ring therebetween. The containment wall may comprise a sealing member on its upper surface. The sealing member may be an O ring, or a pliable material integral with the containment wall.

In a preferred embodiment of the present invention, the sample well contains one or more openings or grooves and an overflow ring for collecting excess sample as it is squeezed out by the closing cover plate. Preferably, the cover plate is attached to the tab so that the sample proximate the cover plate hinge makes contact with the cover plate first, and as the cover plate closes, excess sample is squeezed out through the two grooves and into the overflow ring.

Other features and advantages of the present invention will become apparent from the following detailed description. It should be understood, however, that the detailed description and the specific examples while indicating preferred embodiments of the invention are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

This summary does not necessarily describe all necessary features of the invention but that the invention may also reside in a sub-combination of the described features.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other features of the invention will become more apparent from the following description in which reference is made to the appended drawings wherein:

Figure 1 is a perspective view of a system incorporating an apparatus of the present invention for measuring Hemoglobin A1c.

Figure 2 is a perspective view illustrating the sample tab of the apparatus of Figure 1.

5

Figure 3 depicts various aspects of an embodiment of a sample tab of the present invention. **Figure 3A** illustrates an oblique view of the sample tab. **Figure 3B** exhibits a side view of the sample tab.

10 **Figure 4** depicts various aspects of an alternate embodiment of a sample tab of the present invention. **Figure 4A** illustrates an oblique view of the sample tab. **Figure 4B** exhibits a side view of the sample tab.

15 **Figure 5** depicts various aspects of an alternate embodiment of a sample tab of the present invention. **Figure 5A** illustrates an oblique view of the sample tab. **Figure 5B** exhibits a side view of the sample tab.

DESCRIPTION OF PREFERRED EMBODIMENT

The invention relates to a tab for retaining a sample for analysis. More particularly, the present invention provides a sample tab and a method for sample analysis using a variety of instruments including a spectrophotometer or a microscope.

The following description is of a preferred embodiment by way of example only and without limitation to the combination of features necessary for carrying the invention into effect.

10

The present invention provides a sample tab that may be used for the determination of a substance within a sample using spectrophotometric or microscopic analysis. The sample tab comprising a base plate, a well disposed on the base plate and a cover plate. In a broad aspect, the present invention also provides an apparatus for determining the concentration of a substance in a sample where the apparatus comprises, a sample housing for receiving a sample tab; a radiation source; and radiation detector, operatively coupled with a system for providing a determination of the substance within the sample based on the determination of transmitted or reflected radiation.

15

According to one embodiment of the present invention, the sample housing comprises a block with a slit for inserting the sample tab. The sample tab consists of a base plate with a well on the base plate for containing the sample and a cover plate which can be placed over the well prior to inserting the sample tab in the housing, preferably, the cover plate closes automatically when inserted in the sample housing. The well may be of any desired shape and of any suitable volume.

20

25

The present invention also provides a method of determining the concentration of a substance within a sample using a sample tab.

30

For example, which is not to be considered limiting in any manner, the sample tab as described herein may be used to determine the occurrence or concentration of

any substance within a biological or non-biological sample. Preferably the sample is a fluid sample, for example but not limited to blood, or a semi-solid sample. A non-limiting example is provided herein where the sample tab of the present invention may be used, in combination with a spectrophotometer, to test a diabetic patient's 5 compliance with their insulin dosing regime by quantifying the amount of HbA_{1c} and Hb contained in a blood specimen taken from the patient, without further treatment of the specimen, and comparing the concentration of HbA_{1c} and Hb within the sample. In this non-limiting example, an elevated ratio of HbA_{1c} reflects a lack of patient 10 compliance. However, it is to be understood that the sample tab of the present invention may be used to determine the concentration of any substance within a sample using spectrophotometric, microscopic, or other analysis that requires that a sample be retained within a translucent or transparent tab. Furthermore, the sample tab as described herein may comprise at least one surface that reflects incident 15 radiation. Examples of other biological samples that may be determined include, but are not limited to whole blood, plasma, serum, synovial fluid, cerebral spinal fluid, urine, lymph, mucus, faeces, and semen. However, non-biological samples may also be readily tested as described herein. Examples of non-biological samples include, 20 but are not limited to dairy products, for example, milk, cheese, cottage cheese, yoghurt, or ice cream, or beverages, or semi-solid foods. Non-limiting examples of substances that may be detected in these samples include Hemoglobin, one or more proteins, albumin, globulin, fat, lactose etc. An example of a non-limiting measurement that can be made is hematocrit in blood.

According to the present invention, there is provided a method of 25 quantification of one or more substances within a sample, comprises the steps of:

- i) generating a calibration algorithm for each of the substances to be determined;
- ii) obtaining a sample and placing the sample into a sample tab;
- iii) measuring with a spectrophotometer, absorbance of radiation by each of the 30 substances in the sample; and
- iv) incorporating the absorbance measured in step (iii) in the algorithms generated in (i), and calculating the concentration of the substances in the sample.

For example which is not to be considered limiting, if the sample is blood, then the concentration of HbA_{1c} and Hb may be determined. In this case the method of quantification of the one or more chemical compounds comprises the steps of:

5

- i) generating a calibration algorithm for each of the HbA_{1c} and Hb;
- ii) obtaining a blood sample and placing the blood sample into a sample tab;
- iii) measuring with the spectrophotometer, absorbance of radiation by each of the HbA_{1c} and Hb in the blood sample; and
- 10 iv) incorporating the absorbance measured in step (iii) in the algorithms generated in (i), and calculating the concentration of the HbA_{1c} and Hb in the sample.

Alternatively, one algorithm can be developed for the ratio of HbA_{1c} to Hb expressed as % HbA_{1c}.

15

16
17
18
19
20
21
22
23
24
25

According to a method of the present invention, quantification includes calculation of the first derivatives of at least two portions of a spectrum generated from a scan for each of the chemical compounds being determined, for example but not limited to, HbA_{1c} and Hb which may then be used to calculate each of the HbA_{1c} and Hb concentrations in the sample. Similarly, PLS (Partial Least Squares) or PCA (Principal Components Analysis) may be used depending on the analyte being analysed.

25

According to another aspect of the present invention, the method as described herein can be used with reflectance instead of absorbance. In the case of reflectance, either the base plate or the cover plate may have a reflective surface or may be made of reflective material. Such a reflective surface or material could include any suitable reflective coating, for example, but not limited to, a ceramic coating, barium sulfate, Spectralon™, Spectraflect™, or Duraflect™.

30

Turning now to the sample housing within a spectrophotometer and sample tab, as may be seen in Figure 1, electromagnetic radiation from the spectrophotometer is delivered to the sample in the sample tab (5) through a source or incident optical

5 fibre (60) while the sample rests in a sample tab holder (70) within a sample housing (80). The electromagnetic radiation passing through the sample tab and specimen is received by a receiving optical fiber (90), and processed further to determine concentrations of one or more substances within the sample.

surface of the base plate. The well may be of any desired volume and may be of any shape;

c) at least one overflow groove or opening in the wall (20) of the well permitting drainage of excess sample from within the well;

5 d) a cover plate (40) having at least a portion that permits transmission or reflectance of electromagnetic radiation.

In use, a sample is retained in the well between the base plate and the cover plate so that electromagnetic radiation may pass through the base plate, through a 10 sample in the well, and the cover plate. However, it is within the scope of the present invention that the radiation beam may travel through the sample, and be reflected off either the base plate or cover plate thereby doubling the path length of the radiation beam. By doubling the path length, a reduced volume of sample may be used during analysis. Either the base plate or the cover plate may have a reflective surface, or may 15 be made of, reflective material.

The sample well defined by a closed wall contains one or more openings or grooves and an overflow ring for collecting excess sample as it is squeezed out by the closing cover plate. Preferably, the cover plate is attached to the tab so that the sample proximate the cover plate hinge makes contact with the cover plate first, and as the cover plate closes, excess sample is squeezed out through the grooves, which are preferably situated at the side where the cover plate makes final contact with the rest of the tab, and into the overflow ring. The hinged design helps the sample tab slide into the receptor of an instrument, such as a spectrophotometer.

25 Referring now to Figure 2, there is shown an aspect of an embodiment of the sample tab of the present invention. Shown in Figure 2, is sample tab (5) comprising base plate (45), cover plate (40) and sample well (10) defined by closed wall (15). Sample well (10) may be of any volume required, for example, but not limited to, a 30 size sufficient to allow a drop of blood to fill the well, preferably with some excess. The sample well may also be large enough to accommodate about 10mL of a sample, for example urine or a beverage. It must be understood that these are just non-limiting

examples of sample sizes. In an embodiment which is not meant to be considered limiting in any manner, the well is circular and comprises dimensions of about 4 mm in diameter and about 2 mm in depth. Overflow openings or grooves (20) in closed wall (15) allow excess sample to flow out of sample well (10) when cover plate (40) is closed over sample well (10) and base plate (45). A second wall, such as, but not limited to, a containment wall (37) may be employed to retain the sample that overflows sample well (10), into an overflow ring (30) to prevent leakage of fluid from the sample tab, while permitting a sample of sufficient volume to fill the well. In this regard, the vertical height of containment wall (37) is less than or equal to the height of closed wall (15) defining sample well (10), more preferably it is equal to the height of closed wall (15) defining sample well (10). Cover plate (40) is preferably attached to base plate (45) by hinge (50) or other suitable attachment means known in the art. However, a non-hinged cover plate may also be used. The cover plate may be snapped on to the base plate as described below.

15

16

17

18

19

20

21

22

23

24

25

The sample tab may be manufactured from any suitable material known in the art, for example, but not limited to, a transparent, translucent material, such as glass, plastic or a combination thereof, or a reflective material. If the base plate and cover plate are transparent or translucent, then it is preferred that the base plate, and cover plate comprise a transparent or translucent plastic, such as but not limited to polypropylene, polycarbonate, polyethylene, or polystyrene, however, a glass plate may also be used. If either of the base plate or cover plate is reflective, then a reflective material, for example but not limited to a ceramic coating, barium sulfate, Spectralon™, Spectrareflect™, or Duraflect™ may be used for one of the base or cover plates.

30

Optionally, the sample tab of the present invention may comprise a locking member to lock cover plate (40) to the base plate (45). The locking member may comprise a portion of the cover plate, base plate or both. Further, the locking member may reversibly or irreversibly lock the cover to the base plate. Any locking member known in the art may be employed with the sample tab of the present invention, for example, but not limited to those as shown in Figures 3-5. The use of a containment

wall ensures that the sample is retained within the sample tab and reduces contamination between samples. Furthermore, by locking the cover plate of the sample tab in a closed position, the sample tab may be readily disposed of after use without sample leakage, or the sample tab may be used in a vertical position, for 5 example within a cuvette holder adapted for use within spectrophotometers.

Referring now to Figure 3, there is shown an alternate aspect of an embodiment of the present invention. In Figure 3A, there is shown a perspective view of a sample tab (5) with cover plate (40) positioned over base plate (45) and revealing 10 a well (10) defined by closed wall (15), overflow grooves (20), overflow-ring (30; Figures 1 and 2), and hinge (50). Figure 3B shows a side view of a sample tab (5) wherein cover plate (40) is open. Also shown in Figure 3B is a locking member (60) which permits cover plate (40) to be fastened to base plate (45). In the aspect of the embodiment shown in Figure 3B, the locking member (60) comprises a circular ring, capable of frictionally engaging containment wall (37), thereby reversibly attaching cover plate (40) to base plate (45), preventing the escape of a sample from the sample tab. However, as would be evident to someone of skill in the art, the locking member (60) comprising a circular ring may be attached to the base plate (45) in a variety of ways, for example, but not limited to, frictionally engaging a protrusion located on the outside of containment wall (37), or frictionally engaging a recessed groove in the base plate (not shown), adjacent to and below containment wall (37).

When the cover plate is closed over the well, and attached to the base plate, it is preferred that the top surface (35) of the containment wall (37) seals against the 25 lower surface of the cover slip. However, the locking member (60) may also be used to help seal the sample within the sample tab should any leakage occur past the containment wall (37). The embodiment shown in Figure 3 shows a hinged cover plate, however, it is to be understood that cover plate (40) comprising locking member (60) may be separate from base plate (45), and the cover plate may be attached to the 30 base plate after a sample is introduced into well (10). Since the cover plate is attached to the base plate, the final sample tab assembly serves as one unit.

If it is required that the sample be effectively sealed within well (10), then the upper surface of containment wall (37) may be modified to comprise a sealing member (35), for example an "O ring" that fits within a grooved upper surface of the containment wall, the top surface of the containment wall (37) may be made of a 5 softer pliable material, for example silicon, yet integral with the base plate. Alternatively, the top surface (35) of the containment wall (37) may be lubricated so that when cover slip (40) is attached to base plate (45) a seal is formed between base plate (45) and cover slip (40). The use of a containment wall ensures that the sample is retained within the sample tab and reduces contamination between samples. 10 Furthermore, by locking the cover plate of the sample tab in a closed position, the sample tab may be readily disposed of after use without sample leakage.

Referring now to Figure 4, there is shown an alternate aspect of an embodiment of the present invention. Figure 4A shows a perspective view, and in 15 Figure 4B, a side view, of a sample tab (5) with cover plate (40) and base plate (45). In these figures, cover plate (40) is open revealing well (10) defined by closed wall (15), overflow grooves (20), and containment wall (37). Also shown in Figure 4B are locking members (60) which permit cover plate (40) to be attached to base plate (45). In the aspect of the embodiment shown in Figures 4A and 4B, locking members (60) 20 comprise one or more clips capable of frictionally engaging base plate (45), at a corresponding recess (65) within the base plate, thereby locking cover plate (40) to base plate (45) and preventing the escape of a sample from well (10). Locking members (60) may be positioned so that when engaged with the base plate at the corresponding recess (65), they do not extend below the lower surface of the base plate, so that a smooth bottom surface is obtained. Such a smooth surface may be 25 required for sliding the sample tab into a receptor of an apparatus, or for microscopic viewing.

If it is required that the sample be effectively sealed within well (10), then the 30 upper surface of containment wall (37) may be modified to comprise a sealing member (35), for example an "O ring" that fits within a grooved upper surface of the containment wall, the top surface of the containment wall (37) may be made of a

softer pliable material, for example silicon, yet integral with the base plate. Alternatively, the top surface (35) of the containment wall (37) may be lubricated so that when cover slip (40) is attached to base plate (45) a seal is formed between base plate (45) and cover slip (40). As described above, the use of a containment wall and 5 optionally a locking cover plate ensures that sample leakage is kept to a minimum.

Referring now to Figure 5, there is shown another aspect of embodiment of the present invention. In Figure 5A, there is shown a perspective view, and in Figure 5B a side view, of sample tab (5) with cover plate (40) positioned over base plate (45). In 10 Figure 5A, cover plate (40) is open revealing well (10) defined by closed wall (15), overflow grooves (20), containment wall (37) and hinge (50). Also shown in Figure 5B is locking member (60) which permits cover plate (40) to be attached to base plate (45) by association with a corresponding mating recess (65) positioned on the base plate. In the aspect of the embodiment shown in Figures 5A and 5B, locking member 15 (60) comprises a clip capable of frictionally engaging mating recess (65) and locking cover plate (40) to base plate (45), preventing the escape of the sample. The mating recess may extend through the base plate (45), and engage the bottom surface of the base plate, or the locking member may engage a snap portion within recess (65) and not extend thorough the base plate. A smooth bottom surface may be required for sliding the sample tab into a receptor of an apparatus, or for microscopic viewing. It is to be understood that the locking member (60) may be positioned in the base plate, and recess (65) positioned on the cover slip if desired.

If it is required that the sample be effectively sealed within well (10), then the 25 upper surface of containment wall (37) may be modified to comprise a sealing member (35) so that when cover slip (40) is attached to base plate (45) a seal is formed between base plate (45) and cover slip (40). In this embodiment, the use of a containment wall ensures that the sample is retained within the sample tab and reduces contamination between samples. Furthermore, by locking the cover plate of 30 the sample tab in a closed position, the sample tab may be readily disposed of after use without sample leakage, or it may be used in a vertical position as required.

Figures 3-5 illustrate a locking member (60) on the cover plate (40) of the sample tab (5) of the present invention. However, it is also possible that locking member (60) may comprise a portion of base plate (45), and that the corresponding recess (65) be positioned on the cover plate (40).

5

The sample tab of the present invention may retain any sample for analysis using any suitable instrument, for example, but not limited to spectroscopic or microscopic analysis. Preferably the sample tab retains a fluid or semi-solid sample, for example, but not limited to non-biological or biological samples. Examples of 10 non-biological samples include, but are not limited to dairy products, for example, milk, cheese, cottage cheese, yoghurt, or ice cream, or beverages, or semi-solid foods. Examples of biological fluids include, but are not limited to whole blood, plasma, serum, sinovial fluid, cerebral spinal fluid, urine, lymph, mucus, faeces, and semen.

15 The embodiments shown in Figures 2-5 are meant to be exemplary rather than limiting in any manner. Those of skill in the art will understand that modifications of the sample tab, base plate, cover plate and locking member, or a combination thereof may be made without departing from the spirit and scope of the present invention, and it is fully intended that such modifications are contemplated by the sample tab of the 20 present invention.

25 The sample tab as described herein may be used within a spectrophotometer using standard methods as known in the art, for example as disclosed in US 5,846,492, US 6,268,910, WO 98/39634 (all of which are incorporated herein by reference). These references disclose the spectrophotometric analysis of a biological fluid within a plastic or polyethylene container, for example blood bag tubing (US 6,28,910), or a pipette tip (WO 98/39634; US 5,846,492). However, it is to be understood that the sample tab as described herein may be readily adapted for other 30 analytical uses including microscopic analysis.

30 The above description is not intended to limit the claimed invention in any manner. Furthermore, the discussed combination of features might not be absolutely

necessary for the inventive solution.

All references are herein incorporated by reference.

5 The present invention has been described with regard to preferred embodiments. However, it will be obvious to persons skilled in the art that a number of variations and modifications can be made without departing from the scope of the invention as described herein.
